UML

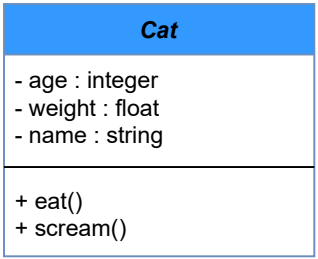
Representing objects with UML

The Unified Modeling Language (UML)

- Standard way to visualize a system
- Visual representation of objects

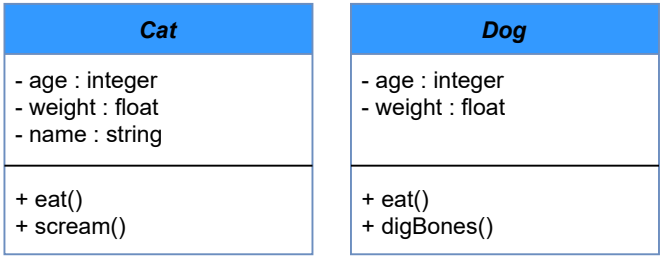
Let's represent an object for **cat**

- The class "Cat"
  - to represent all the cats
  - an instance: a cat
- Attributes
  - age (integer)
  - weight (float)
  - name (string)
- Functions
  - eat()
  - scream()

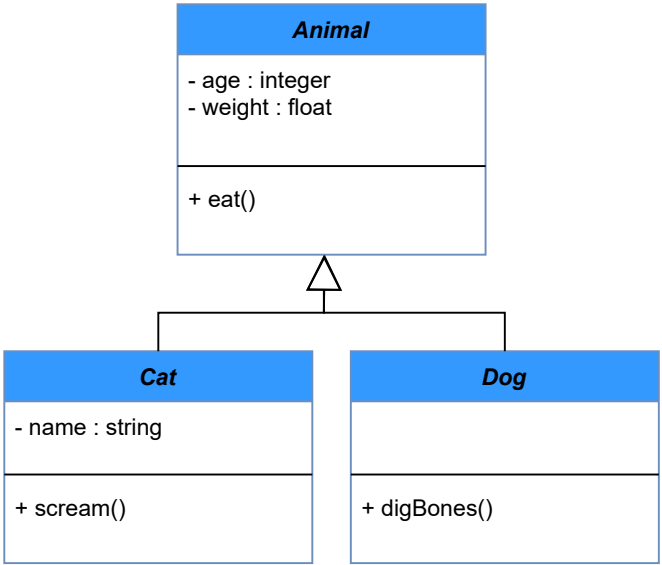


More objects

- The class “Cat”
  - to represent all the cats
- The class “Dog”
  - to represent all the dogs



Code reuse with inheritance



Cats and Dogs are Animals

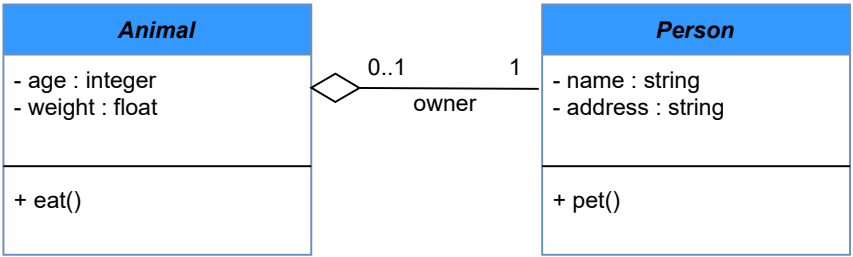
- A Cat is an Animal
- A Dog is an Animal
- Cat and Dog **inherit** from animals

⇒ A subclass inherits all attributes and functions from super class

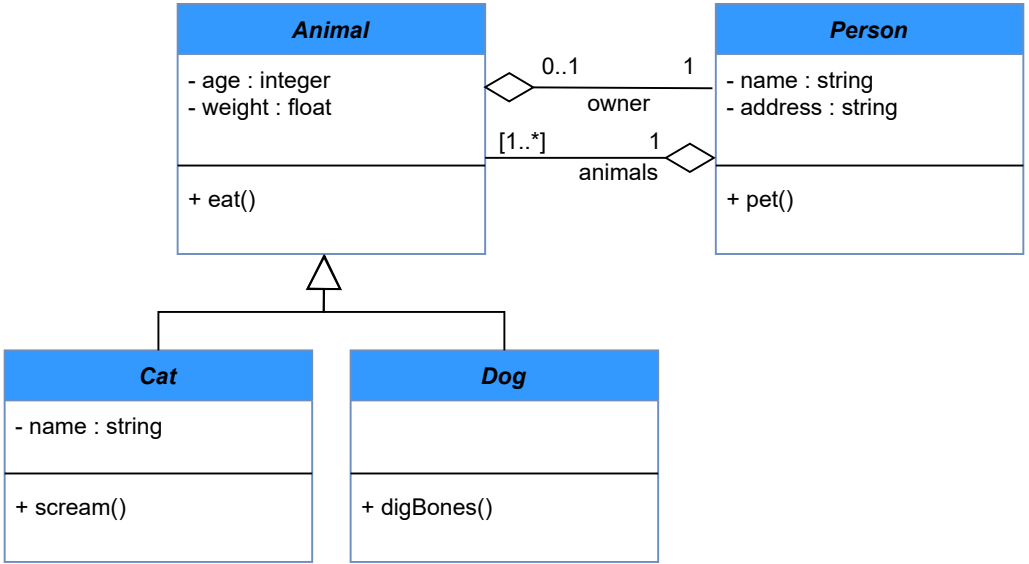
Composition and aggregation

All animal has an Owner

- The class “Animal” as a relation of **aggregation** with the class “Owner”



Full example



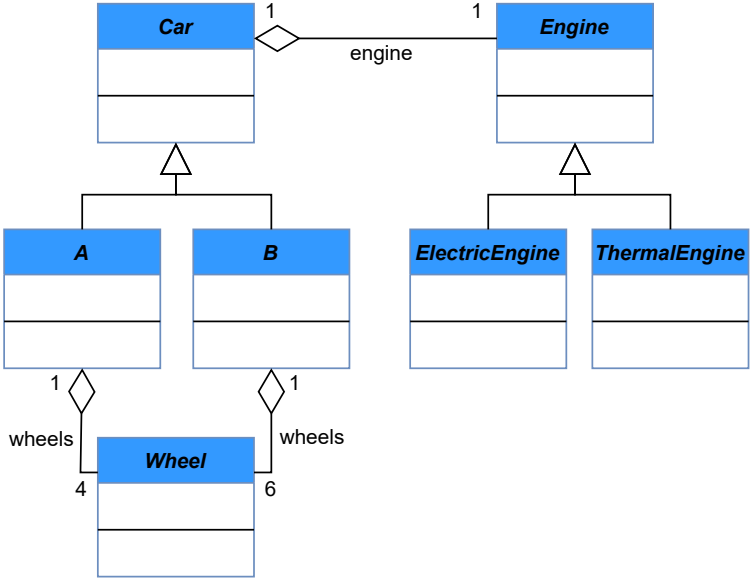
Exercise

Specification

There are two type of cars, A and B. The cars A have 4 wheels, but the car B have 6 wheels. All the cars have an engine that can be or electric or thermal.

Write the UML class diagram corresponding to this example

Correction



Car
1
1
Engine
engine
A
B
ElectricEngine
ThermalEngine
1
1
wheels
wheels
Wheel
4
6

Python

Using Python

Python files: “name.py”

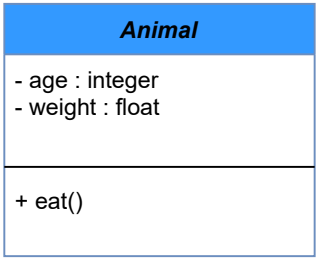
Integrated development environement

- Text editor + CLI
- Spyder: `https://www.spyder-ide.org/`
- PyCharm: `https://www.jetbrains.com/pycharm`

Code example:

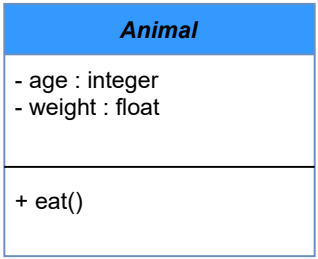
```
1 if __name__ == "__main__":
2     print("Hello world")
```

Class definition



```
1  class Animal:
2
3      def __init__(self, ...):
4          # Constructor
5          ...
6
7      def __str__(self):
8          # Return a string value
9          ...
10
11     def eat():
12         # Behavior
13         ...
```

Class definition



```python
class Animal:

    def __init__(self, age, weight):
        # Constructor
        self.age = age
        self.weight = weight

    def __str__(self):
        return f"I am {self.age} years old,
            and weigh {self.weight} kg"

    def eat(self):
        print("Eat")
```

Class usage

```
class Animal:
    ...

if __name__ == "__main__":
    my_animal = Animal(14, 8.0)
    your_animal = Animal(weight=4.5, age=3)
    print(my_animal.age)
    my_animal.eat()
    print(my_animal)
```

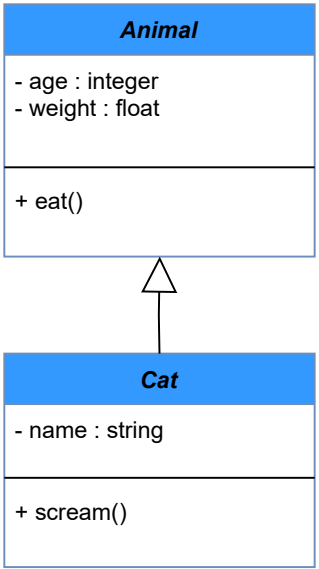
Output:

14

Eat

I am 14 years old, and weigh 4.5 kg

Class definition



```python
class Animal:
    ...

class Cat(Animal):

    def __init__(self, name, age, weight):
        Animal.__init__(self, age, weight)
        self.name = name

    def __str__(self):
        return f"I am {self.name} the cat"

    def scream(self):
        print("Grrrrr")
```

Class usage

```
class Animal:
    ...

class Cat(Animal):
    ...

if __name__ == "__main__":
    lila = Cat("Lila", 14, 8.0)
    lila.eat() # From Animal
    lila.scream()  # From Cat
    print(lila)  # From ?
```

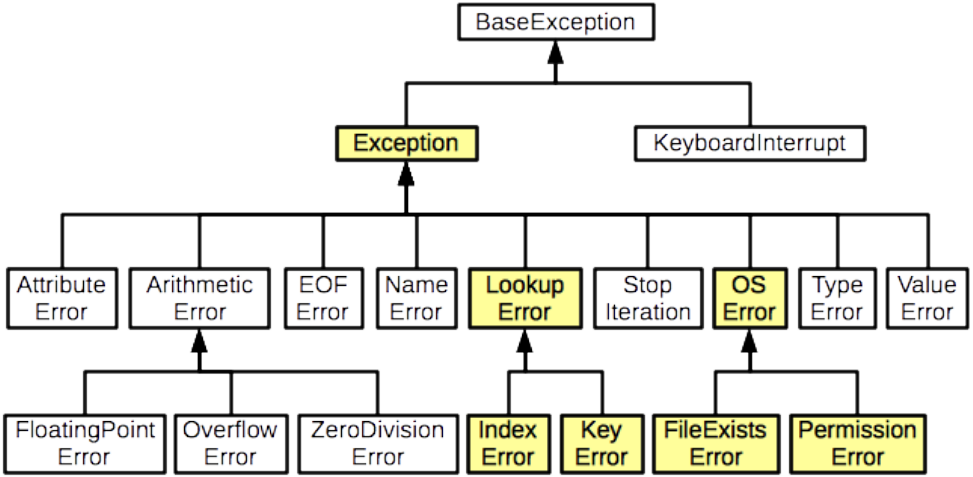
Exceptions

Managing errors

- rising exceptions to control unwanted behavior or definition
- management of exceptions when calling the function using **try** and **except**

```
1  class Animal:
2
3      def __init__(self, age):
4          if (age >= 0):
5              self.age = age
6          else:
7              raise Exception('Negative age are not allowed')
8
9  if __name__ == "__main__":
10     try:
11         Animal(-1)
12     except Exception as e:
13         print(e)
```

Inheritance in exceptions



Static functions

We can define function for a given object or for the whole class

⇒ For an object

```
def purr(self):
    print("ronron")
lila.purr() # To call
```

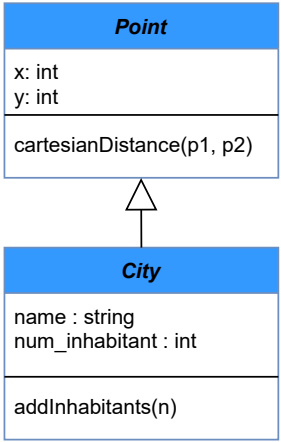
⇒ For a class

```
def hugs(a1, a2):
    print(f"{a1.name} hugs {a2.name}")
Cat.hugs(lila, garfield) # To call
```

Exercise

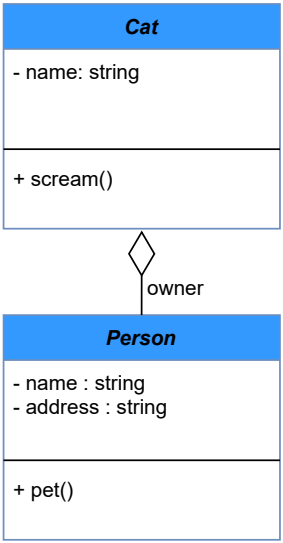
1. Create a class **Point** with attribute x and y corresponding to its coordinate. Write the code for the function __**str**__ and __**init**__. Test these methods.
2. Create a function **cartesianDistance** to compute the cartesian distance between two points. Reminder: cartesian distance of $p1 = (x_1, y_1)$ and $p2 = (x_2, y_2)$ is $\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$
3. Test your function over the two points (0, 5) and (-1, 9)
4. Create a sub-class of Point, named **City**. The cities have a name and a number of inhabitant. Write the code for the function __**str**__ and __**init**__.
5. Create **a function to add** a number of inhabitant in the city.

Correction



Code: `https://jolanphilippe.github.io/course/docs/24-oop/point.py`

Aggregation



```
1  class Person:
2
3      def __init__(self, name, address):
4          self.name = name
5          self.address
6
7  class Cat(Animal):
8
9      def __init__(self, name, age, weight,
           person):
10         Animal.__init__(self, age, weight)
11         self.name = name
12         self.owner = person
```

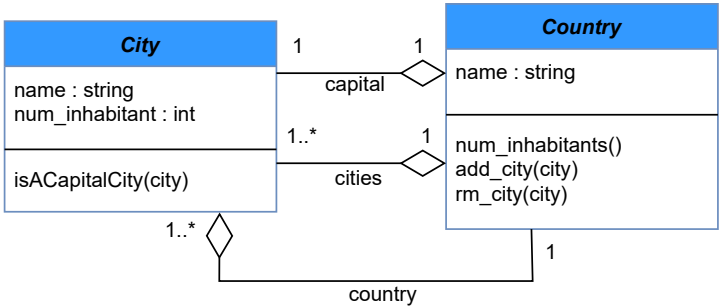
Exercise

1. Create a class **City** which has a name and a number of inhabitant.
2. Create a class **Country**. This class has a capital city and has a list of cities.
3. Create two functions for Country: One to **add** a City, and one to **remove** a City.
4. Write a function that calculates the total **number of inhabitant** in a Country.
5. Add a static function **isACapitalCity** to the class City, that returns True if the City is the capital of a country, False otherwise.
6. Test all your functions.

How to use list in Python, and how to iterate on it.

```
1 my_list = []
2 my_list.append(a)
3 my_list.remove(a)
4 for element in my_list:
5     print(element)
```

Correction



Code: `https://jolanphilippe.github.io/course/docs/24-oop/country.py`

Exercise

Write the Python code of the following UML diagram.
